

## 1 BUSINESS INTELLIGENCE WORKLOAD

The Business Intelligence (BI) workload is the SNB's analytical (OLAP) workload. As such, it defines complex read queries that touch a significant portion of the data (see Section 1.4). Additionally, it defines daily batches of updates over a 33-day period (see Section 1.5 for inserts and Section 1.6 for deletes).

### Related Publications

The BI workload was published in PVLDB 2022 [17].

### Related Software Components

- Datagen (Spark-based): [https://github.com/ldbc/ldbc\\_snb\\_datagen\\_spark](https://github.com/ldbc/ldbc_snb_datagen_spark)
- Driver and reference implementations: [https://github.com/ldbc/ldbc\\_snb\\_bi](https://github.com/ldbc/ldbc_snb_bi)

## 1.1 Overview

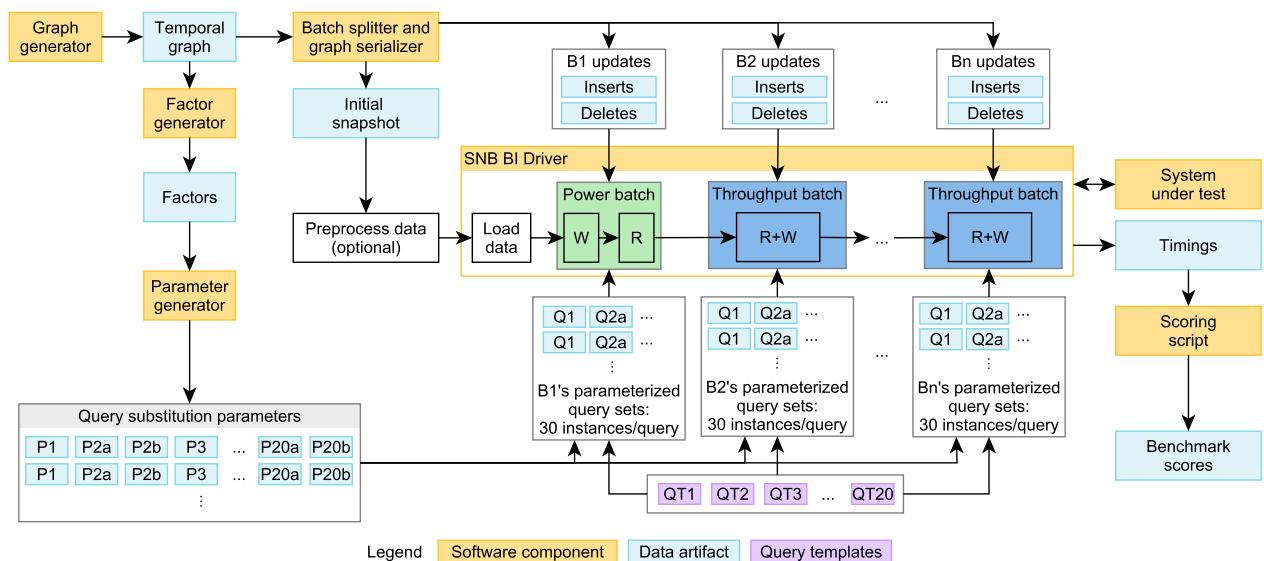

Figure 1.1: Main software components and data artifacts of the benchmark and their connection to the workflow executed by the BI benchmark driver.

An overview of the BI workload is shown in Figure 1.1. The rules for auditing workload implementations are given in ??.

## 1.2 Read Query Templates

SNB BI consists of 20 parameterized *read query templates*, referred to as *queries*. These search for graph patterns (often implying join-heavy operations on many-to-many edges), traverse hierarchies, and compute cheapest paths (a.k.a. weighted shortest paths). Additionally, they include filtering, grouping, aggregation, and sorting operators. While all queries explore a large portion of the graph, they only return the top-*k* (typically 20 or 100) results, keeping their result sizes compact to avoid emphasizing the client-server network protocol's role in the benchmark [13].

### 1.2.1 Choke Point-Based Design Methodology

LDBC's query design process relies on the use of *choke points* (??), i.e. challenging aspects of query processing. SNB BI includes 38 choke points divided into 9 categories: aggregation performance, join performance, data access locality, expression calculation, correlated subqueries, parallelism and concurrency, graph specifics, language features, and update operations. Their coverage is shown in ???. In the following, we discuss two challenges that are particularly prevalent in graph workloads.

#### 1.2.1.1 Explosive and redundant multi-joins

In recent years it has become clear that graph pattern matching, or equivalent multi-join queries over many-to-many relationships, typically generate very large intermediate results when executed with traditional join algorithms. This is especially the case for cyclical join graphs (corresponding to cyclic graph queries). It was proven in theory [11] and shown in practice [18, 9, 5] that “worst-case optimal” multi-join algorithms can avoid these large intermediates and outperform traditional joins. Following this, there has been increased attention on *redundancy* in join results (even when produced by worst-case optimal joins), which can be eliminated using *factorized* query processing techniques [2, 12, 8]. Graph pattern matching queries that contain large join patterns will trigger these phenomena.

#### 1.2.1.2 Expressive path finding

SNB BI contains queries that require an efficient implementation of shortest path finding between many pairs. Expressing such queries requires a query language which supports either path finding or recursion. The underlying system implementation must then handle this with an optimized execution strategy, as recursing to try all paths will not scale. As some of this path finding includes on-the-fly computed edges (joins) between nodes, the queries can benefit from *path expressions*, as proposed in Oracle's PGQL language [15] and as part of the GQL and SQL/PGQ languages [3]. The path finding required by SNB BI not only tests connectivity (as supported in SPARQL), but also requires returning the *cheapest cost* along weighted paths (necessitating SPARQL extensions [10]).

### 1.2.2 Analysis of Selected Queries

In order to defeat trivializing complex query performance by query caching, benchmarks can use both frequent updates (which require invalidating caches or maintaining cached intermediates) as well as parameterized query templates. The BI workload features update batches, so parameterized *read query templates* are necessary to guard against this between the batches. In this section, we analyze four read query templates.

*Notation:* We denote the query parameters with the \$ symbol and discuss their generation in Section 1.3.

#### 1.2.2.1 Q11: Friend triangles

**BI 11** imposes two key difficulties. First, systems should efficiently filter the knows edges based on the location of their endpoint Persons (Country \$country) and the date range. Second, given a large number of knows edges even after filtering, efficient enumeration of personA–personB–personC triangles (a cyclic subgraph query) requires worst-case optimal multi-joins.

#### 1.2.2.2 Q14: International dialog

**BI 14** imposes different challenges depending on whether Countries \$country1 and \$country2 are correlated or anti-correlated (Section 1.3.3.1). For the ranking, *top-k pushdown* can be exploited: once a result for a City in \$country1 is obtained, extra restrictions in a selection can be added based on the value

of this element. As the score of two Persons does not depend on any query parameters, precomputing and maintaining it as an attribute on the knows edge can be beneficial.

#### 1.2.2.3 Q18: Friend recommendation

**BI 18** is inspired by Twitter’s recommendation algorithm [7]. Implementations of this query can exploit factorization: systems can count the number of mutual friends without explicitly enumerating all  $\langle \text{person1}, \text{personM}, \text{person2} \rangle$  tuples.

#### 1.2.2.4 Q20: Recruitment

**BI 20** performs *graph projection* [1]. Instead of materializing this graph in the database, systems may represent it using a compact in-memory structure such as CSR (Compressed Sparse Row) [16]. To perform the cheapest path computation, a single-source shortest path algorithm (starting from \$person2), such as Dijkstra’s algorithm, can be used. As the projected graph is independent of query parameters, precomputing and maintaining it can be beneficial.

### 1.3 Parameter Curation for BI Queries

#### 1.3.1 The Need for Parameter Curation

A disadvantage of executing the same read query template with different parameters is that the intermediate results and runtimes can be severely influenced by the parameter values. This is particularly the case in SNB BI with its explosive joins, skewed out-degrees, skewed value distributions, correlated value distributions, and structural correlations. Moreover, the updates (including cascading deletes) can significantly change the portion of the graph reached by the same query executed at different times. In order to keep query performance understandable we need to actively *curate* parameters, such that different parameters executed at different logical times still lead to stable and, therefore, understandable results. We achieve this through *parameter curation* [6, 4], a data mining process of looking for parameter values with suitably similar characteristics.

#### 1.3.2 Parameter Generation Steps

Our parameter curation process is a two-step process: we first generate *factors* followed by the *parameters* (Figure 1.1). These components are executed for each scale factor and are independent of the serialization format/layout of the data set.

##### 1.3.2.1 Factor Generator

The factor generator produces 21 *factor tables* containing summary statistics from the temporal graph, e.g. the number of Persons per City or the number of Messages per day for each Tag.

##### 1.3.2.2 Parameter Generation

To find suitable substitution parameters that (presumably) lead to the same amount of data access and thus similar runtimes, we first identify the factor table containing the summary statistics of the query’s parameters. For example, Q14’s template uses the parameters Country \$country1 and Country \$country2. Therefore, we use the countryPairsNumFriends factor table which contains \$country1, \$country2 pairs and the number of friendships on Person lives in \$country1 and the other lives in \$country2. Using this table, we select the  $p$ th percentile from the distribution as the *anchor*, then rank the rest of the distribution based on their absolute difference from the anchor and take the top- $k$  values. We shuffle the values using a hash function to avoid introducing artificial locality, where e.g. subsequent queries start in nodes from the same ID range. Listing 1.1 shows the SQL query implementing the parameter generation for Q14a.

### 1.3.3 Parameter Curation for Graph Queries

We discuss two parameter curation cases that are particularly important in graph data management.

#### 1.3.3.1 Correlated vs. Anti-Correlated Parameters

Our parameter curation provides a straightforward way of selecting start entities which are affected by (structural or attribute-level) correlation vs. anti-correlation: corresponding parameters can be found by selecting a high vs. low percentile as the anchor in the parameter generation query. For example, for Q14 (Section 1.4), we selected variant *a* to  $p = 0.98$  (correlated) and variant *b* to  $p = 0.03$  (anti-correlated).

#### 1.3.3.2 Path Queries

SNB BI queries Q15, Q19, Q20 include cheapest path finding queries computed between given (sets of) Persons. These queries are particularly challenging for parameter curation: if there is no path between the two endpoints, query runtimes are significantly higher as the search has to traverse an entire connected component to ensure that no path exists. Moreover, the presence of a path between two nodes *at a given time* does not guarantee that it will always exist during the benchmark execution as deletions can render the endpoints of a path unreachable.

### 1.3.4 Query Variants

12 queries have a single variant, while 8 queries have two variants, yielding a total of 28 query variants. As a rule of thumb, variants *a* are expected to produce a longer runtime while variants *b* are expected to be simpler. Variants of Q2, Q8, Q16 are parametrized with a flashmob vs. a non-flashmob date. Variants of Q14 and Q19 select correlated vs. non-correlated Countries/Cities. Q10's variants differ in degree (a start Person with an average number of friends vs. only a few friends), while Q15's variants have different path lengths and time intervals (4 hops and one week vs. 2 hops and one month). Q20a selects endpoints where it is guaranteed that *no path exists*, while Q20b selects ones where there is guaranteed that a path exists.

### 1.3.5 Scalability and Reproducibility

#### 1.3.5.1 Scalability

The *factor generator* is part of the SNB Datagen and runs after the *temporal graph* has been created. It is implemented in Spark for distributed execution. While its computations use expensive, aggregation-heavy queries, the derived factor tables are *compact*, e.g. SF10 000 has only 20 GiB of factors in compressed Parquet format, the equivalent of approximately 100 GiB in CSV format, i.e. 1% of the total data set size. The *parameter generator* queries are executed in DuckDB [14], which supports vertical scalability and is capable of running the parameter generation for SF10 000 using less than 512 GiB memory.

```
SELECT country1, country2
FROM (
  SELECT
    country1,
    country2,
    abs(frequency - (
      SELECT percentile_disc(0.98) WITHIN GROUP (ORDER BY frequency) AS anchor FROM countryPairsNumFriends
    )) AS diff
  FROM countryPairsNumFriends
  ORDER BY diff, country1, country2
)
ORDER BY md5(concat(country1, country2))
```

**LIMIT** 50

Listing 1.1: Parameter generation SQL query for Q14a.

### 1.3.5.2 Reproducibility

It is important to guarantee that the parameter curation process is reproducible. To this end, we leverage that the Datagen and, consequently, the factor generator are reproducible. To ensure that the parameter generation queries yield deterministic results we define a total ordering in each query. To provide deterministic shuffling we base the ordering on MD5 hashes (instead of the actual attribute values), see Listing 1.1.

BI 1	query	BI / read / 19														
BI 2	title	Interaction path between cities														
BI 3	pattern	<p>Find the shortest paths between all pairs of Persons in city1 and city2. The weight of a knows edge is based on the number of interactions between its Persons: <math>\text{knows.weight} = \max(\text{round}(40 - \sqrt{\text{numInteractions}}), 1)</math></p>														
BI 4																
BI 5																
BI 6		<p>Example for finding a path between person1 and person2</p>														
BI 7		<p>Given two Cities with IDs <math>\\$city1Id</math>, <math>\\$city2Id</math>, find Persons <math>person1</math>, <math>person2</math> living in these Cities (respectively) with the <i>cheapest</i> interaction path between them.</p>														
BI 8		<p>The cheapest path is equivalent to the <i>weighted shortest</i> path. It is computed on a subgraph of the Person-knows-Person graph with the edge weights based on the number of interactions. An <i>interaction</i> is a direct reply Comments from one Person to Messages by the other Person. Only knows edges with at least one interaction between their endpoint Persons are considered. For these, the weight of a knows edge is defined as: <math>\max(\text{round}(40 - \sqrt{\text{numInteractions}}), 1)</math></p>														
BI 9		<p>If there are multiple pairs of people with cheapest paths that have the same total weight, return all of them.</p>														
BI 10		<p><i>Note:</i> Interactions are counted both ways, e.g. if Alice knows Bob, Alice writes 2 reply Comments to Bob's Messages and Bob writes 3 reply Comments to Alice's Messages, their total number of interactions is 5 and the weight of the knows edge is 38.</p>														
BI 11		<p><i>Remark:</i> Determinism is ensured by using square root followed by rounding. For all integers between 1 and 100 000, the square root's fractional part is more than 10e-5 from 0.5, where the rounding could be non-deterministic based on floating point inaccuracies. As 10e-5 is significantly larger than the machine epsilon of IEEE 754 floats (both 32- and 64-bit), the floating point inaccuracies have no chance to affect the derived integer edge weights.</p>														
BI 12		<table border="1"> <tr> <td>1</td> <td><math>\\$city1Id</math></td> <td>ID</td> <td>(a) Small Cities within the same Country</td> </tr> <tr> <td>2</td> <td><math>\\$city2Id</math></td> <td>ID</td> <td>(b) Larger Cities from different Countries</td> </tr> </table>			1	$\$city1Id$	ID	(a) Small Cities within the same Country	2	$\$city2Id$	ID	(b) Larger Cities from different Countries

## 1.5 Insert Operations

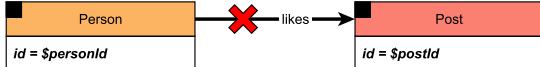

Insert operations consist of individual inserts for each entity type. Implementations typically use the same format as the one for loading the initial snapshot of the data set.

## 1.6 Delete Operations

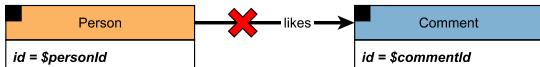

### Updates / delete / 1

DEL 1	query	Updates / delete / 1		
DEL 2	title	Remove person and its personal forums and message (sub)threads		
DEL 3	pattern			
DEL 4				
DEL 5				
DEL 6				
DEL 7				
DEL 8				
description		Remove a Person with ID \$personId and its edges (isLocatedIn, studyAt, workAt, hasInterest, likes, knows, hasMember, hasModerator, hasCreator). Additionally, remove the Album and Wall Forums whose moderator is the Person and remove all Messages the Person has created in the rest of the Forums (Groups).		
params		1	\$personId	
CPs		9.3, 9.4, 9.5		
relevance		<ul style="list-style-type: none"> <li>• Removal of a Person removes Forums of type “Walls” and “Albums” but not “Groups”, which can continue if even the founder has left the network. For Groups, the hasModerator edge is deleted. We have discussed various approaches to appoint a new moderator, e.g.           <ol style="list-style-type: none"> <li>1. choose member at random from the set of existing group members or</li> <li>2. the member with the oldest group join date becomes the moderator. However, to keep the generator and the workload simple, currently no moderator is selected, leaving the group without a moderator.</li> </ol> </li> <li>• Removal of a Person removes all Posts/Comments they are creator of this could result in the removal of a Comment in the middle of a thread.</li> </ul>		

## Updates / delete / 2

DEL 1	query	Updates / delete / 2								
DEL 2	title	Remove post like								
DEL 3	pattern									
DEL 4	description	Given a Person with ID \$personId and a Post with ID \$postId, remove the likes edge between them.								
DEL 5	params	<table border="1"> <tr> <td>1</td> <td>\$personId</td> <td>ID</td> <td></td> </tr> <tr> <td>2</td> <td>\$postId</td> <td>ID</td> <td></td> </tr> </table>	1	\$personId	ID		2	\$postId	ID	
1	\$personId	ID								
2	\$postId	ID								
DEL 6	CPs	9.4								
DEL 7	relevance	Removal of a likes edge is a rare event, e.g. people accidentally liking a Post, this can be reflected by the relative frequency of the operation.								
DEL 8										

## Updates / delete / 3

DEL 1	query	Updates / delete / 3
