BI 3	pattern	For each pair of countries, calculate the cost as a sum of cases #1–4. Cases that have a match add to the final score with the specified value. Each case only counts once, multiple matches do not increase to the score.

BI 13	description	Consider all pairs of people (<i>person1</i>, <i>person2</i>) such that (1) they know each other, (2) one is located in a City of <i>\$country1</i>, and (3) the other is located in a City of <i>\$country2</i>. For each City of <i>\$country1</i>, return the highest scoring pair. If there are multiple top-scoring pairs in a city, return the pair with the lowest (<i>person1.id</i>, <i>person2.id</i>) using a lexicographical ordering. The score of a pair is defined as the sum of the subscores awarded for the following kinds of interaction. The initial value is <i>score</i> = 0. 1. <i>person1</i> has created a reply Comment to at least one Message by <i>person2</i>: <i>score</i> += 4 2. <i>person1</i> has created at least one Message that <i>person2</i> has created a reply to: <i>score</i> += 1 3. <i>person1</i> liked at least one Message by <i>person2</i>: <i>score</i> += 10 4. <i>person1</i> has created at least one Message that was liked by <i>person2</i>: <i>score</i> += 1 Consequently, the maximum score a pair can obtain is: 4 + 1 + 10 + 1 = 16.
